

Searching

Searching is a process of finding given values position in a list of values.

Type of searching

- i) Linear search
 - ii) Indexed Linear Search
 - iii) Binary search
- 1) Linear search / Sequential search

It is a basic and simple search algorithm. It compares the element with all the other element given in the list. If the element is matched, it returns the index value, -1 otherwise.

algo :

Linear Search (A[], key, lb, ub)

```
for (k = lb, k <= ub; k++)
```

```
    if (key == A[k])
```

```
        return k;
```

```
}
```

```
return lb - 1;
```

```
}
```

11) Indexed linear search

In this searching method, first of all an index file is created, that contains some specific group or division is required to record when the index is obtained then the partial indexing takes less time cause it is located in a specified group

1	1

9.	3
1 -	4
	5
	6
	7
	8
	9
	10
	11

III) Binary Search

It is a searching algorithm used in a stored array by repeatedly dividing the search interval in half.

The idea of binary search is to use the information that the array is sorted and reduce the time complexity to $O(\log n)$.

BinarySearch(A[], lb, ub, key)

 low = lb

 high = ub

 mid = (low + high) / 2

 while (A[mid] != key && low <= high)

 if (item < A[mid])

 high = mid - 1;

 else

 low = mid + 1;

 mid =

 (mid + low) / 2;

 if (A[mid] == key)

 return mid;

 else

 return low - 1;

Hashing

Hash table

- Hash table is one of the most important data structure that use a special function known as a hash function that map a given values with a key to access a element faster.
- A hash table is a DS that stores some information, and the information has basically two main component i.e., key and values. The hash table can be implemented with the help of an array.
- The efficiency of mapping depends upon the hash function used for mapping.
- Complexity is always one.

function % no of element in array

Suppose the key value is x and the value is a phone number, so when we pass the key in the hash function the index is,

$$\text{index} = \text{hash}(x)$$

Drawback of hash function

A hash function assign each value with a unique key. Sometimes hash table use an imperfect function that passes a collision because the hash function generates the same key of two different values!

hash function = $2k+3$

$$\begin{aligned} 23 &= (2(23) + 3) \% 10 \\ &= 49 \% 10 \end{aligned}$$

$$\begin{aligned} 33 &= (2(33) + 3) \% 10 \\ &= 69 \% 10 \\ &= 9 \end{aligned}$$

(Collision)

Hashing

→ It is one of the searching technique that use a ~~constant~~ constant time. The time complexity in hashing is $O(1)$.

The main function

- The main idea behind the hashing is to create the key value pairs.
- If the key is given then the algorithm computes the index at which the value would be stored. It can be written as:

$$\text{index} = \text{hash}(\text{key})$$

There are three ways of calculating hash functions

- Division Method
- Folding Method
- Mod Square Method

Division Method

In the division method, the hash function can be defined as

$$h(K_i) = K_i \% m$$

where, $i = \text{no of keys}$

$K = \text{key}$

$m = \text{size of hash table}$

$h = \text{hash function}$

Collision

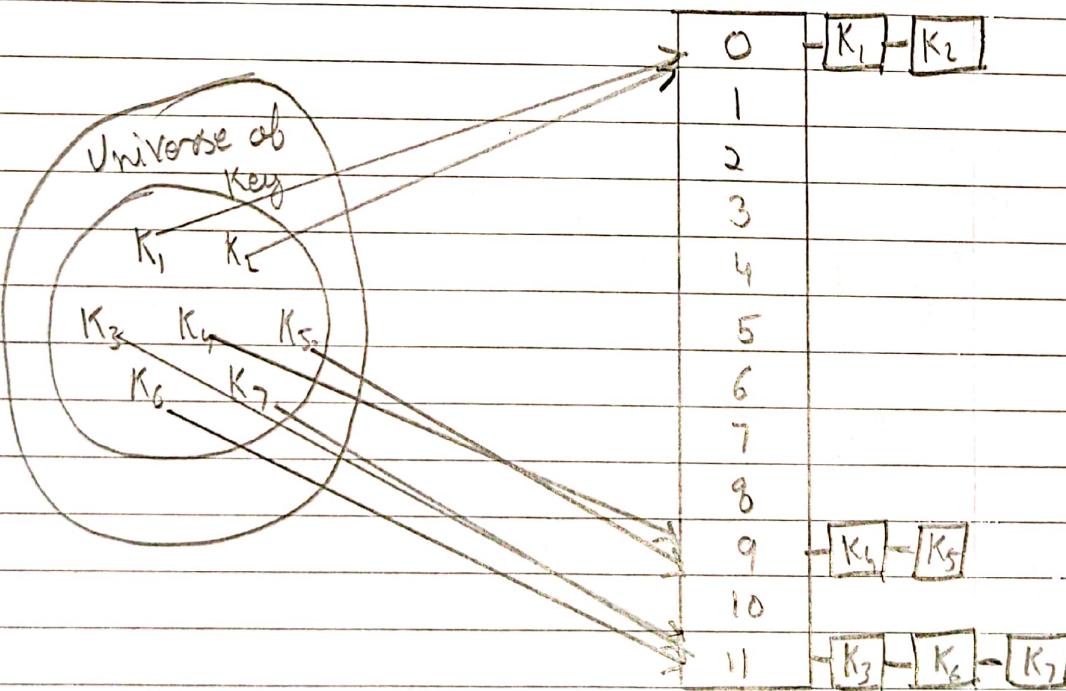

A collision occurs when more than two pieces of data in a hash table share ~~the~~ the same hash value.

The following are the collision techniques

- open hashing (close addressing)
- close hashing (open addressing)

Open hashing

In open hashing one of the method is used to resolve the collision. It is known as chaining method.

(84)

(84)

Example: Suppose we have a list of key values.

$$A = 3, 2, 9, 6, 11, 13, 7, 12$$

$$h(k) = 2k + 3$$

$$m = 10$$

key	location (Index)
3	$(2(3)+3)\%10 = 9$
2	$(2(2)+3)\%10 = 7$
9	$(2(9)+3)\%10 = 1$
6	$(2(6)+3)\%10 = 5$
11	$(2(11)+3)\%10 = 5$
13	$(2(13)+3)\%10 = 9$
7	$(2(7)+3)\%10 = 7$
12	$(2(12)+3)\%10 = 7$

3	
4	
5	6 11
6	
7	2 7 12
8	
9	3 13

Closed hashing

In closed hashing three techniques are used to resolve a problem.

→ Linear probing

It is one of the forms of open addressing. As we know that each cell in the hash table contains a key value pair, so when the collision occurs by mapping a new key, then linear probing technique search for the closest free location and adds a new key to the empty cell. In this case, searching is performed sequentially, starting from the position where the collision occurs till the empty cell is not found.

Example: $A = \{3, 2, 9, 6, 11, 13, 7, 12\}$

$$m=10, \quad h(k) = 2k+3$$

Prob

$$1 \quad (2(3)+3) \% 10 = 9$$

$$1 \quad (2(2)+3) \% 10 = 7$$

$$1 \quad (2(9)+3) \% 10 = 1$$

$$1 \quad (2(6)+3) \% 10 = 5$$

$$2 \quad (2(11)+3) \% 10 = 5 \quad \text{Collision \#1}$$

$$2 \quad (2(13)+3) \% 10 = 9 \quad \text{Collision \#0}$$

$$2 \quad (2(7)+3) \% 10 = 7 \quad \text{Collision \#8}$$

$$6 \quad (2(7)+3) \% 10 = 7 \quad \text{Collision \#2}$$

13	0
9	1
12	2
	3
	4
6	5
11	6
3	7
7	8
3	9

→ Quadratic Probing

It is an open addressing technique that uses quadratic polynomial for searching until an empty slot is found. It can be also defined as that it allows the insertion at first space from $(i + i^2) \% m$ where $i = 0$ to $m - 1$.

Example:

$$A = \{3, 2, 9, 6, 11, 13, 7, 12\}$$

$$m = 10; \text{ hash}(k) = 2k^2 + 3$$

$$(3*2+3) \% 10 = 9$$

$$(2*2+3) \% 10 = 7$$

$$(2*9+3) \% 10 = 1$$

$$(2*6+3) \% 10 = 5$$

$$(2*11+3) \% 10 = 5 \text{ collision}$$

when $i=0$

$$(0+0^2) \% 10 = 0$$

$$\text{when } i=1, (1+1^2) \% 10 = 2$$

$$(13*2+3) \% 10 = 9 \text{ collision}$$

$$\text{when } i=0, (8+0^2) \% 10 = 8$$

$$\text{when } i=1, (9+1^2) \% 10 = 0$$

$$(7*2+3) \% 10 = 7 \text{ collision}$$

$$\text{when } i=0, (7+0^2) \% 10 = 7$$

$$\text{when } i=1, (7+1^2) \% 10 = 8$$

$$(2*12+3) \% 10 = 7 \text{ collision}$$

$$\text{when } i=0, (7+0^2) \% 10 = 7$$

$$\text{when } i=1, (7+1^2) \% 10 = 8$$

$$\text{when } i=2, (7+2^2) \% 10 = 1$$

$$\text{when } i=3, (7+3^2) \% 10 = 6$$

$$\text{when } i=4, (7+4^2) \% 10 = 3$$

13	0

2	
12	3
4	
6	5
11	6
2	7
17	8
3	9

→ double probing

It is an open addressing technique which is used to avoid the collision when the collision occurs then this technique use the secondary hash of the key. It use one hash value as an index to move forward until the empty location is found.

In double hashing two hash functions are used.

Suppose $h_1(K)$ is one of the hash function is used to calculate the location. whereas $h_2(K)$ is another hash function, it can be defined as to insert K_i at first free place from

$$(U + V * i) \% m,$$

where, $i = 1$ to $m-1$

U = location computed using the hash function $h_1(K)$

$$V = h_2(K)$$

Example:

$$A = \{3, 2, 9, 6, 11, 13, 7, 12\}$$

$$m = 10,$$

$$h_1(K) = 2k+3$$

$$h_2(K) = 3k+1$$

(88)

Date _____

key	m	v	c		
3	$(2 \times 3) \% 10 = 9$		1	9	0
2	$(2 \times 2 + 3) \% 10 = 7$		1	9	1
9	$(9 \times 2 + 3) \% 10 = 1$		1	9	2
6	$(6 \times 2 + 3) \% 10 = 5$		1	11	3
11	$(11 \times 2 + 3) \% 10 = 5$	$(3 \times 11 + 1) \% 10 = 4$	3	12	4
13	$(13 \times 2 + 3) \% 10 = 9$	$(3 \times 13 + 1) \% 10 = 0$		6	5
7	$(7 \times 2 + 3) \% 10 = 7$	$(3 \times 7 + 1) \% 10 = 2$			6
12	$(12 \times 2 + 3) \% 10 = 7$	$(3 \times 12 + 1) \% 10 = 7$	2	2	7
					8
				3	9

for key = 11

$$i = 0$$

$$(5 + 4 \times 0) \% 10 = 5$$

$$i=1 (5 + 4 \times 1) \% 10 = 4$$

$$i=2 (5 + 4 \times 2) \% 10 = 3$$

for key = 13

Since: $v = 0$, 9 will be returned
in every iteration from $i=0$ to $m-1$
 \therefore 13 can't be inserted in hash
table

for key = 7

$$i=0, (7 + 2 \times 0) \% 10 = 7$$

$$i=1, (7 + 2 \times 1) \% 10 = 9$$

$$i=2, (7 + 2 \times 2) \% 10 = 1$$

$$i=3, (7 + 2 \times 3) \% 10 = 3$$

$$i=4, (7 + 2 \times 4) \% 10 = 5$$

$$i=5, (7 + 2 \times 5) \% 10 = 7$$

$$i=6, (7 + 2 \times 6) \% 10 = 9$$

$$i=7, (7 + 2 \times 7) \% 10 = 1$$

$$i=8, (7 + 2 \times 8) \% 10 = 3$$

$$i=9, (7 + 2 \times 9) \% 10 = 5$$

since, we checked all places
for 7 but no one is
empty hence 7 can't be
inserted into hash table

when key = 12

~~$i=0, (7 + 7 \times 0) \% 10 = 7$~~

$i=1, (7 + 7 \times 1) \% 10 = 4$

Sorting

Insertion Sort

```

for (i=1; i<n; i++)
{
    temp = a[i];
    j = i-1;
    while (j >= 0 && a[j] > temp)
    {
        a[j+1] = a[j];
        j--;
    }
    a[j+1] = temp;
}

```

Complexity :- Best : $O(n)$
 Average : $O(n^2)$
 Worst : $O(n^2)$
